

# Estimation of Sample Size and Power for Dunnett's Testing Setups with Unequal Effect Sizes

Marcus Vollmer

Institute of Bioinformatics, University Medicine Greifswald

Adaptive Designs and Mutiple Testing Procedures

04 October 2018, Bremen

## Content

1 Sample Size Estimation

- 2 Dunnett's Test
- 3 Idea of unbalanced testing
- 4 What is the optimal set of sample sizes?
- 5 A case example for animal test proposals
- 6 How to organize an intelligent search for an optimal set of group sizes?

# **1. Sample Size Estimation**

## The three Rs

Principles were developed over 50 years ago as a framework for humane animal research

### Replacement

Methods which avoid or replace the use of animals

### Reduction

Methods which minimise the number of animals used per experiment

### Refinement

Methods which minimise the suffering and improve animal welfare

## The three Rs

Principles were developed over 50 years ago as a framework for humane animal research

### Replacement

Methods which avoid or replace the use of animals

### Reduction

Methods which minimise the number of animals used per experiment

### Refinement

Methods which minimise the suffering and improve animal welfare

## German animal protection law (came into force in 1972)

duty of disclosure 13% prescribed by law (e.g. approval of pharmaceuticals, routine test of vaccines)

subject to approval 87%
 Administrative regulation for execution of animal protection law
 8.3 The animal welfare officer should ensure, that appropriate biometrical methods will be deployed during the planning of the experimental project.

## German animal protection law (came into force in 1972)

duty of disclosure 13%
 prescribed by law (e.g. approval of pharmaceuticals, routine test of vaccines)

subject to approval 87%

# Administrative regulation for execution of animal protection law

14.1.3.1 The commission have to support the competent authority about their decision to approve animal experiments; in their statement they should comment in particular, whether it is scientifically substantiated, that [...] no more animals were included in panning of the experiment than essential, to answer the question in consideration of biometrical methods.

# 1. Sample Size Estimation **Sample Size Estimation in R**

## R:pwr

| Function       | Coverage                               |
|----------------|--|
| pwr.2p.test    | Two proportions (equal n)              |
| pwr.2p2n.test  | Two proportions (unequal n)            |
| pwr.anova.test | Balanced one way ANOVA                 |
| pwr.chisq.test | Chi-square test                        |
| pwr.f2.test    | General linear model                   |
| pwr.p.test     | Proportion (one sample)                |
| pwr.r.test     | Correlation                            |
| pwr.t.test     | T-tests (one sample, 2 sample, paired) |
| pwr.t2n.test   | T-test (two samples with unequal n)    |

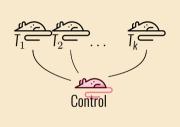

# 2. Dunnett's Test

# 2. Dunnett's Test A niece of ANOVA

# Multiple comparison test by Charles Dunnett (1955)

- Post-hoc-Test after ANOVA
- Compare k treatment arms against a control group  $H_{0i}: \mu_i = \mu_0$
- Similar to performing multiple t-tests
- Designed to hold the family-wise error rate FWER=P(number of falsely rejected  $H_0 \ge 1$ )  $\le \alpha$
- General rule (same effect size, equal variance):  $\frac{n_0}{n} \approx \sqrt{k} \frac{\sigma_0}{\sigma}$

R:multcomp and R:DTK

R:DunnettTests

Performing the special testing problem with unequal group sizes. The computation of the p-values includes the consideration of a multidimensional t-distribution and the adjustment for multiple testing. A procedure for sample size estimation is missing.

Conducting sample size calculation, but only with identical treatment effect size and pre-specified sample allocation ratio. In other situations, simulation-based evaluation is suggested, which needs great computational effort.

## Power calculation with R:DunnettTests

```
1 library(DunnettTests)
2
3 #Compare group means of four treatment arms to a control arm (upper one-sided
      tests)
4 k
      = 4 # Number of treatment arms
5
  m11
      = 2 # Assumed mean of each treatment arm
 m_{11}O = 1 # Assumed mean of the control arm
6
 n
      = 20
8 n0 = 20
9 \text{ sigma} = 1
10
 df = n * k + n0 - k - 1
11
12 # get power of the test
13 (power = powDT(r=k, k, mu, mu0, n, n0, "means", sigma, df, testcall="SD"))
```

R:multcomp

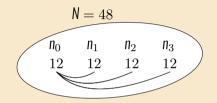

# **3. Idea of unbalanced testing**

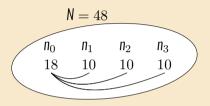

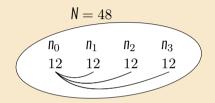

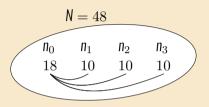

$$t = \frac{\bar{x_0} - \bar{x_i}}{\sigma \sqrt{\frac{1}{n_0} + \frac{1}{n_i}}} = \frac{\Delta \bar{x}}{\sigma} \frac{1}{\sqrt{\frac{2}{12}}} = 2.45 \frac{\Delta \bar{x}}{\sigma}$$

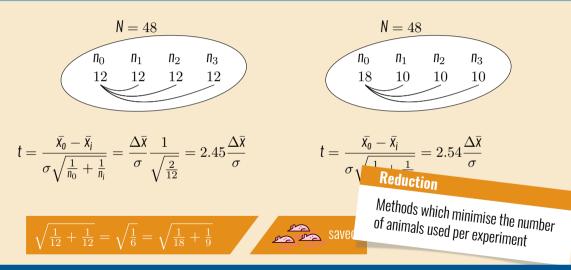

$$t = \frac{\bar{x_0} - \bar{x_i}}{\sigma \sqrt{\frac{1}{n_0} + \frac{1}{n_i}}} = \frac{\Delta \bar{x}}{\sigma} \frac{1}{\sqrt{\frac{2}{12}}} = 2.45 \frac{\Delta \bar{x}}{\sigma}$$

$$t = \frac{\bar{x_0} - \bar{x_i}}{\sigma\sqrt{\frac{1}{18} + \frac{1}{10}}} = 2.54 \frac{\Delta \bar{x}}{\sigma}$$

$$\sqrt{\frac{1}{12} + \frac{1}{12}} = \sqrt{\frac{1}{6}} = \sqrt{\frac{1}{18} + \frac{1}{9}}$$
 saved

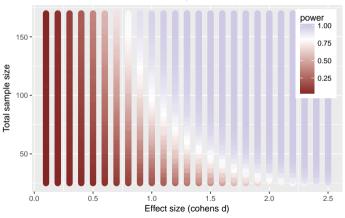

# 4. What is the optimal set of sample sizes?

# 4. What is the optimal set of sample sizes? **Results**

- Maximal power estimated by random sampling
- All possible partition sets {n<sub>0</sub>, n} with N = n<sub>0</sub>+k·n included

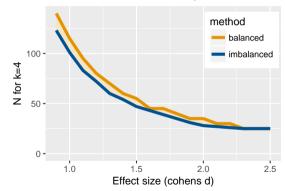

Optimal sample size for unequal group sizes (k=4)

# 4. What is the optimal set of sample sizes? **Results**

- Balanced partitions sets compared against imbalanced partitions
- Difference in total sample size at 80% power

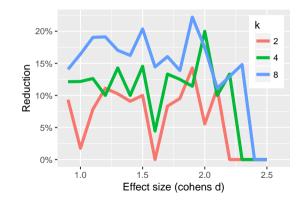

Benefit of imbalanced sample sizes

# 4. What is the optimal set of sample sizes? **Results**

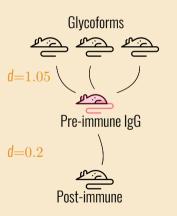

- Balanced partitions sets compared against imbalanced partitions
- Difference in total sample size at 80% power
- Reduction increases with number of treatment groups k

# Passive immunization with glycoforms of IgG

Immunoglobulin G immunization of pneumococcal infected mice Measurements from IVIS Spectrum Imaging

## Assumptions

- Negative control Pre-immune lgG:  $\mu_0 = 4.58$
- Negative control Post-immune:  $\mu_1 = 5.73$
- 3 Glycoforms:  $\mu_{2,3,4} = 3.57$
- Equal variance:  $\sigma = 0.96$

# 6. How to organize an intelligent search for an optimal set of group sizes?

The aim is to determine the sample sizes for multiple treatment groups with different effect sizes (different means and unequal variances). A necessary statistical power of 80% is expected. Ideas for finding the minimal set of group sizes in Monte Carlo experiments:

## **Random search**

Start with initial size Sample new position based on derived statistical power

### **Modified grid search**

Evaluate given parameter sets – start with coarse grid – refine grid – increase accuracy (number of simulations)

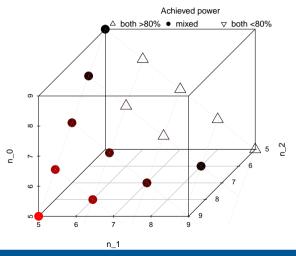

## **Topological concept**

Bottom-up or top-down procedure using the topology of different sets of sample sizes

# 6. How to organize an intelligent search for an optimal set of group sizes? **Topological Concept**

- lllustration of integer partitions with  $N = n_0 + n_1 + n_2 = 19$
- $(n_0, n_1, n_2)$  are individual group sizes

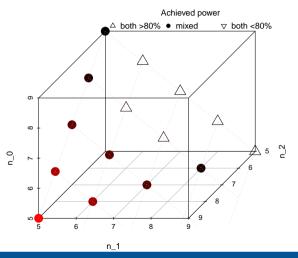

## 6. How to organize an intelligent search for an optimal set of group sizes? Topological Concept

- Illustration of integer partitions with  $N = n_0 + n_1 + n_2 = 19$
- ( $n_0, n_1, n_2$ ) are individual group sizes
  - (6, 5, 8) has the following neighbors in the lower integer partition with N = 18:

 $(5,5,8)\text{,}\,(6,4,8)\text{,}\,(6,5,7)$ 

For those partitions we already know that the power is less than the power for (6,5,8).

### 6. How to organize an intelligent search for an optimal set of group sizes? **Topological Concept**

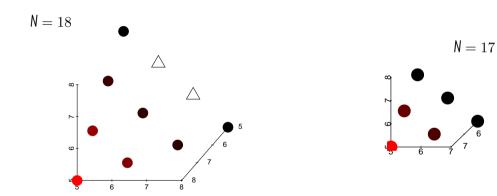

# 6. How to organize an intelligent search for an optimal set of group sizes?

# **Topological Concept**

# **Topological Concept**

# Closing remarks

- It needs roughly 500,000 samples to estimate the power precisely up to the first decimal place
- An intelligent search at different levels of integer partitions of size N can massively reduce the computational size
- It is the objective of constructing a random search with the use of topological relations and precision levels

... work in progress ...
